GEORGIN

Sûreté des Procédés Industriels

SHORT FORM

www.georgin.com

History

GEORGIN has two areas of expertise : industrial instrumentation and the interfacing of measurement signals in hazardous area.

Marc-Aurèle Andrieux
Chairman

Founded by Marcel Georgin in 1939

"Les Régulateurs Georgin" has grown by gradually diversifying its activities for more than 80 years.

- 1965 : Creation of the Physique department, specialised in measurement and regulation (pressure and temperature)
- 1970 : Creation of the Physelec department, specialised in intrinsic safety relays
- 1993 : Creation of the NDT department (Nuclear – Defense – Transport)
- 2006 : First SIL declaration
- 2012 : Creation of the CIAG Instruments subsidiary in Germany
- 2016 : Opening of Georgin Asia Pacific (branch office)
- 2020 : CIAG becomes Georgin GmbH (Germany)

Georgin has been well renowned in France and worldwide for more than 80 years

For its expertise in the measurement and control of pressure and temperature, in the processing, conditioning and security of electrical signals, in industry, military shipbuilding, railways and electricity (production and transmission of nuclear, thermal and hydraulic electricity).

Our strategy is to consolidate our position as an international benchmark in the SAFETY OF INDUSTRIAL PROCESSES.

Georgin, working for you

At every step of your developments, our team is at your side to:

- offer information and advice on the selection of hardware,
- provide commercial support through our technical expertise,
- perform made-to-measure studies of even the most specific applications,
- provide technical assistance with the installation of our devices and systems,
- regularly maintain your Georgin instruments, thanks to our responsive customer service.

Contents

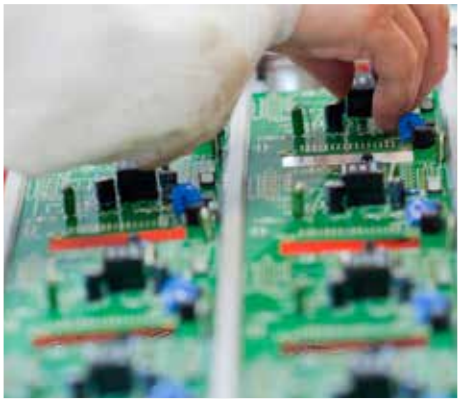
In pictures

Since it was founded, GEORGIN has built a tradition for uncompromising quality in all its products. A combination of technical excellence and responsiveness to the needs of industry enable innovations that make a difference.

Employees who perform and listen carefully in a human-sized company.

A central geographical location 5 km from Paris and 13 km from Orly airport.
A global presence through 3 subsidiaries and a network of over 40 partners.

Products made to measure in France with individual inspection and testing of every product.



Pressure switches

Pressure is applied to the sensing element ES. Its position then changes, acting on the flexible arm LP. The force produced in this way is balanced by the spring RG, adjusting the set point. As the set point is approached, the change in force disturbs the balance LP, acting on the switch CT.

The action of a second spring RE, acting on the flexible arm LP, increases the gap of the switch(es). The force produced by the dead band spring can be adjusted. For differential functions, it offsets the two switches.

A sensing element is closer to the process.
Bellows-actuated technology offers high repeatability. It is recommended for stable processes, not subject to pulses or pressure surges.

Diaphragm-actuated technology meets the constraints of processes involving pulsating phenomena or subject to pressure surges, and is suited to controlling low or very low pressures.

The 316L stainless steel Bourdon tube is used to control very high pressures of up to 1,000 bar.

Temperature switches

The temperature is measured by a direct bulb or differentially by a capillary.

According to the so-called vapour pressure law, the temperature is converted into pressure in the bulb and into force by metal bellows. The variation in position acts on the flexible arm LP. The force produced in this way is balanced by the spring RG, adjusting the set point. As the set point is approached, the change in force disturbs the balance of the flexible arm LP, acting on the contact . The action of a second spring RE, acting on the flexible arm LP, increases the gap of the switch(es). The force produced by the dead band spring can be adjusted. For differential functions, it offsets the two switches.

This technological choice produces short response times and measurement that is insensitive to the ambient temperature around the device.

Energy

Thanks to its broad range of technically advanced products, GEORGIN has become durably established in the energy sector.

Its expertise, certifications (HAF604) and qualifications (K3 and K3-ad) have enabled Georgin to grow in line with the development of nuclear energy. Based on its customers' faith in the company, Georgin can offer genuinely durable solutions.

Railways

GEORGIN has collaborated with manufacturers to adapt its products to the demands and requirements of rolling stock (compact, high resistance to vibrations).

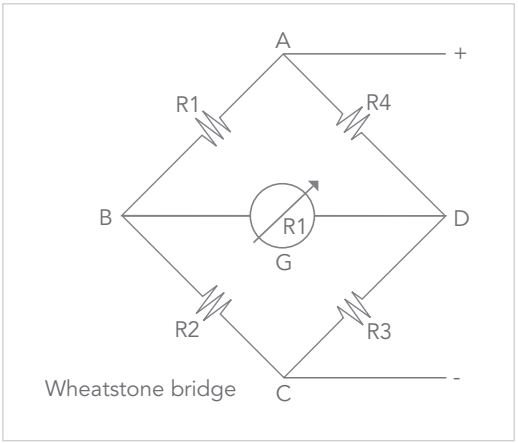
Military shipbuilding

GEORGIN equipment meets the demanding environmental requirements of surface ships, SNA and SNLE from military fleets.

As a specialist in the military sector, GEORGIN commits to and maintains its supplies throughout the life of the installations it equips.

Pressure transmitters

Measuring pressure consists of converting the force applied by a fluid into a usable unit of measurement. Georgin offers a broad range of remote surveillance transmitters based on piezo-resistive sensors. The pressure applies stress to the sensor, creating a measurable variation in the resistance.



Wheatstone bridge

Various types of supports can be considered :

The TR and GR type pressure transmitters are equipped with a thick-film ceramic sensor with a Wheatstone bridge. These sensors offer a dry cell with no filler liquid and constitute an economical solution for a multitude of applications across industry.

The SR^2 is also available with stainless steel parts in contact with the fluid. The piezo-resistive sensor is immersed in a hydraulic liquid. The deformation of the diaphragm by the external pressure causes the hydraulic pressure of the liquid around the piezo-resistive sensor to vary. This measurement method is particularly well suited to the detection of low pressure and can withstand high overload factors.

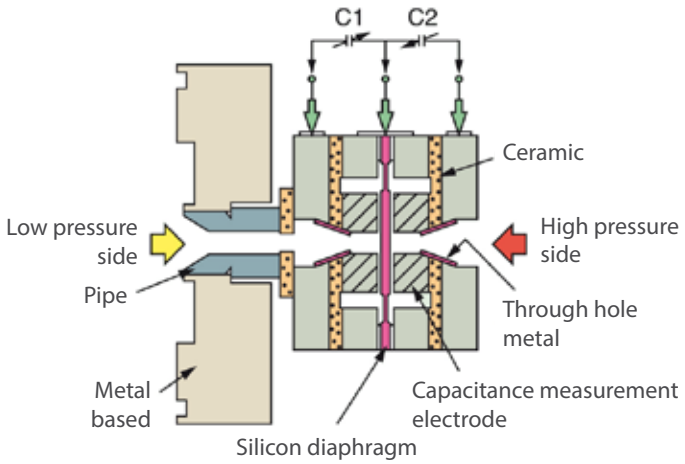
Process transmitters

Measuring pressure consists of converting the force applied by a fluid into a usable unit of measurement. The transmitters in the ProcessX family use capacitive technology.

The effect of the pressure deforms a silicon diaphragm. The plates of the capacitor detect this movement and convert the difference in capacitance between the detector diaphragm and the plates of the capacitor into a 4-20 mA signal. These sensors benefit from a micro-sensor developed from a silicon chip that floats in the throat of the cell. This minimises errors due to the variations in temperature, static pressure and over-pressure that are common in process industry.



The working principle of capacitative sensors

Built of aluminium alloy with a polyester coating or a stainless steel housing

Gas or dust areas

Accuracy up to 0.04% and a stability of ± 0.1% of the maximum scale for 10 years

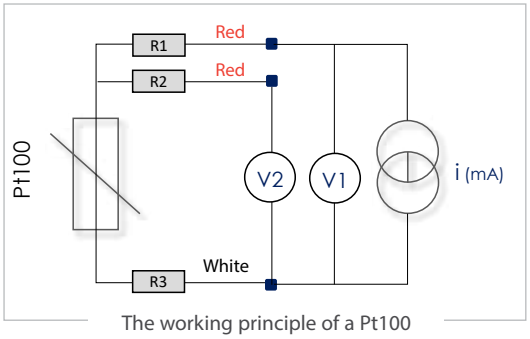
Temperature probes

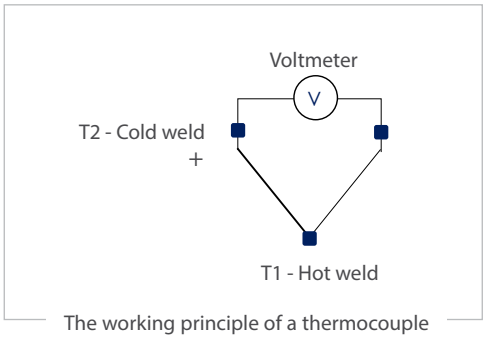
Resistance probes

Resistance temperature probes use the variation in resistance according to the temperature. The RTD100 sensor is a 100 Ohms platinum resistor at 0°C. The measurement current must not exceed 1 mA in order to reduce the risk of the probe self-heating. The three-wire RTD100 is the most widely used option. It is economical and precise. The measurement principle does away with some of the errors caused by the line resistance. The resistance of the three lines (R1, R2 and R3) must be identical. R RTD100 = [V1- (2 x V2)] / I

In the three-wire configuration, the recommended maximum length of the connecting wires is 500 metres. To achieve greater accuracy and limit errors, the use of a TiXo or Tia temperature converter will make it much easier to use the signal. Other configurations, and in particular two- and four-wire, also exist.



The working principle of a Pt100



The working principle of a thermocouple

Thermocouple probes

Thermocouples offer very short response time, and they are compact and robust. Two different types of metals are connected by two junctions at the temperatures T1 and T2. Due to the Seebeck effect, the thermocouple generates a difference of potential that depends on the difference between the temperatures at the junctions. There are several types of thermocouples, according to the temperature range. For example, K thermocouples are made of nickel-chrome / alumel alloy and cover a temperature range from -200°C to 1,100°C. The electrical signals returned by these probes are non-linear and are in the range of the millivolt. Therefore, the quality of measurement depends mainly on the converter used. GEORGIN recommends TiXo 2 or 3, which allows for linearisation and galvanic insulation that protects the signal against any electromagnetic interference.

Temperature transmitters

The TiXo family of temperature transmitters make it easier to use RTD100 or thermocouple sensors and can be integrated into the probe head.
Their main function consists of converting temperature signals into a proportional 4/20 mA signal capable of covering long distances without loss.
The TiXo converters can also diagnose the operational status of the sensor, while changing the signal in the event of a cut.

These devices are designed to be installed close to the process in difficult environments, while guaranteeing a high safety level.
The TiXo has a SIL 2 capacity and can be installed in zone 0 (ATEX II 1 G) or dust zone 20 in its intrinsic safety version B Ex ia.
Installation in zone 2 can be made easier thanks to Ex nA certification.

The easy-to-use programming with ProgressXmanager in the Windows environment, or using FDT/DTM technology, offers a broad range of solutions to configure the type of input, the scale and unit, or online measurement readings or output simulations.

The most advanced version of TiXo3 uses the latest HART 7 communications protocol.

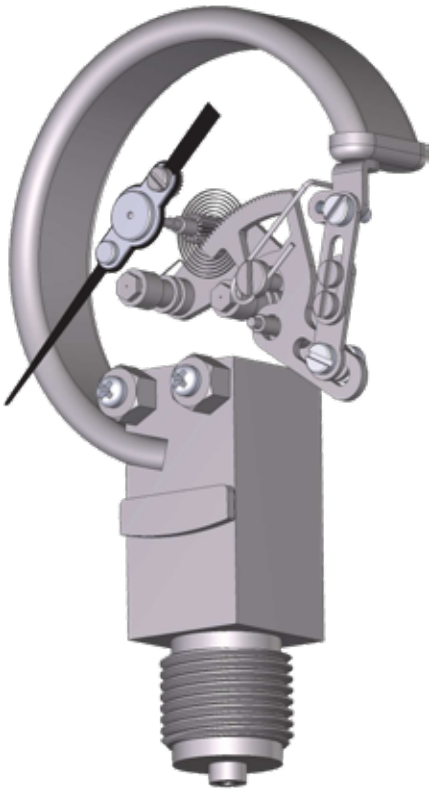
Pressure gauges

In addition to its pressure measurement and control solutions, Georgin also proposes a wide range of industrial pressure gauges.

A Bourdon tube usually forms the heart of these mechanical constructions. These tubes have an oval-shaped cross-section and are curved. The measured fluid acts on the tube. As a consequence, the tube is distorted, and this distortion is sent to the mechanical parts by a connecting rod. The needle rotates proportionally to the value of the pressure.
C-shaped tubes can be used for pressures up to 60 bar. Helical or spiral-shaped tubes are used for higher pressures.

Stainless steel diaphragms can also be used for lower pressures, processes subjected to vibrations and differential constructions. The membrane can also be lined, for example with PTFE, for reasons of compatibility with the fluid.

The pressure gauge is applied and adapted to the requirements of the process around the sensor element.
These requirements may be due to its installation (position of the process connection, assembly supports or damping liquids for vibratory processes), to site safety (safety vents as standard, optional ejector rear panels) or to environmental demands (316 stainless steel or phenolic housing, ATEX constructions, etc.).



The working principle of the Georgin pressure gauge

Thermometers

Georgin's range of thermometers varies according to two main kind of measurement: bimetal and gas expansion.

- The bimetal is a strip of laminar and coiled metal blades with different expansion coefficients. The strip twists in proportion to the variations in temperature and causes the shaft of the thermometer needle to turn.

- A gas expansion product uses a sensor assembly full of liquid that is hermetically closed and pressurised. It is made up of a bulb, a capillary and a Bourdon tube. The movement of the extremity of the tube causes the shaft of the thermometer needle to turn. This design can be used to separate the point of reading from the point of measurement.

In addition to the different types of sensor, these thermometers can also be adapted to the process requirements (direct bulb or remote, housing with a collar or calliper for assembly on a 2" tube, etc.) or environmental requirements (316L stainless steel housing, ATEX certified products, etc.).
All the thermometers can be installed on the process in a thermowell.

Pipework

The analysis of the process specifications often results in the proposal of associated products.

It is important to take all the over-pressures and impulses that could damage the product into consideration. Limiters, dampers and capillaries are accessories that can help to reduce these phenomena.

Excessive temperatures can also harm the proper working order of the associated equipment. In this case, a capillary (cooling of 50 to 70°C/meter, depending on the conditions) or a cooling tower (cooling of 20 to 30°C, depending on the conditions) is used. Siphons are generally used on vapour circuits.

The angled or bent part of the siphon allows for the formation of condensate that protects the measuring instrument. It is also possible to put a coolant inside the bend before it is put into operation.
With superheated water, the siphon is only used to lower the temperature. Siphons can also provide protection against pressure surges. The design of this product is subject to the standard DIN16282.

Regarding the temperature measurement, the use of thermowell facilitates maintenance, calibration and the replacement of sensors, without interrupting the process.
Different types of process connections can be used : screw-on, welded or with flange.
There are two types of build, depending on the application: the sheaths can be mechanically welded for standard applications without any important stress, or drilled for more severe process conditions, such as high temperatures, pressures or flow rates.
They can be machined in different materials: AISI316L, AISI304L, AISI446, AISI310, 316TI, 321, Incoloy, alloy, Hastelloy, Inconel, nickel, Monel, PVC, PTFE, etc.
For certain applications in corrosive environments, the thermowells must have a Teflon, PTFE, HALAR, tantalum or stellite type coating for abrasive applications.

Manifolds

In partnership with the German family-based company AS-Schneider, Georgin markets a broad range of manifolds.
You should choose your 2, 3 or 5 valve manifold according to two essential criteria:

- The design of the valve body that makes installation easier and optimises ease of use by offering ready access to the process in the maintenance phases.
- Consideration of the nature of the fluid, both in the selection of the material of the body (carbon steel, rust-proof or duplex materials, alloys, titanium, etc.) and of the material of the tap seals (PFTE as standard).

As shown below, the coloured rings identify the insulation, drain and balancing. Optional markings can be added to identify the graphite seal, a PCTFE endpiece, reinforced sealing solutions or equipment that can be used with oxygen.

The modularity of the range also allows for a broad choice of taps that meet normative requirements (emissions of volatiles), process safety requirements (OS&Y valve) or site security (anti-vandalism systems).

Every assembly is tested at 1.5 times the maximum service pressure, as per EN 12266-1.

Zener barriers

Zener barriers contribute to the intrinsic safety [Ex i] and are installed in safe areas. Their mission is to limit the level of energy that may appear in an electric circuit routed through a potentially explosive area, whatever the connection established upstream of the barrier.
A barrier is made up of:

- resistors that limit the current
- Zener diodes that limit the voltage
- fuses that protect the components

When a fault voltage is applied across the input terminals of the barrier, the voltage that may appear in the explosive zone is limited by a Zener diode, which is in turn protected by a fuse.
The current is limited to an acceptable value by the resistor.
They can be installed in zone 2, thanks to the Ex nA certification in an IP 54 housing.

Signal interfaces

The galvanically insulated interface is an associated intrinsic safety item of equipment that is installed in a safe zone or in zone 2 in an IP 54 housing, thanks to the Ex nA protection mode. Its mission is to limit the level of energy that may appear in an electric circuit routed through a potentially explosive area, whatever the connection established upstream.

In addition to its energy-limiting function, its facilitates the use of signals in safe areas (e.g., relays), converts signals (e.g., 4/20 mA to 0-10V) or duplicates signals.

Other functions are also available, such as the threshold relay or powering intrinsic safety.

I.S. displays

The loop-powered GeXi displays can be simply inserted in hazardous area in a 4/20 mA intrinsic safety loop in order to read the process value of the connected equipment.

Thanks to their new electronics, the voltage drop they cause in the loop is limited to 1.2 V.

The design of the shallow housing, the removable connection terminals and the new mountings simplify installation in a housing or cabinet and guarantee perfect interchangeability with older-generation appliances or other makes.

They meet a broad range of need in terms of the installation mode, the dimensions of the screen or the numerous available options, such as back-lighting or alarms.

Configuring the devices has been greatly simplified, thanks to an intuitive interface equipped with push buttons on the front panel.

Georgin is the official representative in France of BEKA, which offers a broad range of products, including standalone intrinsic safety clocks, temperature transmitters with displays, meters, tachometers, Modbus/ Fieldbus/Profibus data displays and ATEX sirens and pilot lamps.
